

Hackathon Challenge

29 August, 2026 | Patuakhali Science and Technology University
Duration | 9:00 AM - 3:00 PM

Challenge: MONEY MOVEMENT APPLICATION

Brief:

Design and develop a **Money Movement Application** that allows users to move/transfer/request money between one another through a digital account (with fake balance).

Consider a real-world environment where users depend on the system expecting every transaction to be **correct, reliable and trustworthy**.

Scenario:

Imagine a digital money platform used by a growing community (in 3 years users might be more than 10 million).

Every registered user has an account with a balance. Users should be able to interact with one another financially and conveniently move their money through the application.

A typical user may want to:

"I need to send ₳2,500 to another user."

Another may say:

"My friend owes me ₳1,200. I want to collect it through the application."

Your job is to identify the real world features we need everyday life, implement those features in your app and make it fully functional.

Your Mission:

Build a working **web or mobile application**, including its **backend**, that solves the money-movement problem described above. We intentionally leave the detailed product requirements open.

You are expected to think about the problem from the perspectives of both:
the people using the application and the engineers responsible for making it trustworthy.

Decide what capabilities are necessary for a useful and realistic solution.

Think Beyond the simplistic CRUD app.

Moving money appears simple:

$A \rightarrow \text{₹}500 \rightarrow B$

In a real system, however, things do not always happen exactly as expected. Users may perform actions quickly, networks may behave unexpectedly, multiple activities may happen at the same time, systems may receive unexpected input, and usage may grow far beyond what was originally anticipated.

Your solution should demonstrate how your team thinks about building software for such an environment.

Technical Freedom:

There are **no restrictions** on programming language, framework, database, architecture or development tools

You may use any technologies you believe are appropriate. Use of AI-assisted development tools is also permitted.

However, your team is expected to **understand, explain and defend the solution you build and the engineering decisions behind it.**

Scope:

Your time is limited.

You are **not expected to build a complete banking platform** or integrate with real banks, cards, payment gateways or financial networks.

Treat the application as a **closed money ecosystem** with simulated/fake funds.

Focus on building a small but thoughtful working product rather than a large collection of incomplete features.

Starting Point:

You may fund each user BDT 100,000 in his/her balance automatically while they registers in the application.
